AB Troponin I (**TnI**) is the inhibitory component of the striated muscle Ca2+ regulatory protein troponin (Tn). The other two components of Tn are **troponin C** (TnC), the Ca2+-binding component, and troponin T (TnT), the tropomyosin-binding component. We have used limited chymotryptic digestion to **probe** the local conformation of **TnI** in the free state, the **binary TnC*** **TnI** complex, the ternary **TnC***. **TnI***TnT (Tn) complex, and in the reconstituted Tn*tropomyosin*F-actin filament. The digestion of **TnI** alone or in the TnC***TnI** complex produced initially two major fragments via a cleavage of the peptide bond between Phe100 and Asp101 in the so-called inhibitory region. In the ternary Tn complex cleavage occurred at a new site between Leu140 and Lys141. In the absence of Ca2+ this was followed by digestion of the 1-140 fragment at Leu122 and Met116. In the reconstituted thin filament the same fragments as in the case of the ternary complex were produced, but the rate of digestion was slower in the absence than in the presence of Ca2+. These results indicate firstly that in both free **TnI** and **TnI** complexed with TnC there is an exposed and flexible site in the inhibitory region. Secondly, TnT affects the conformation of **TnI** in the inhibitory region and also in the region that contains the 140-141 bond. Thirdly, the 140-141 region of **TnI** is likely to interact with actin in the reconstituted thin filament when Ca2+ is absent. These findings are discussed in terms of the role of **TnI** in the mechanism of thin filament regulation, and in light of our previous results [Y. Luo, J.-L. Wu, J. Gergely, T. Tao, Biochemistry 36 (1997) 13449-13454] on the global conformation of **TnI**.

AB Troponin I (**TnI**) is the inhibitory component of the striated muscle Ca2+ regulatory protein troponin (Tn). AB To determine the forms of cardiac troponin I (**cTnI**) circulating in the bloodstream of patients with acute myocardial infarction (AMI) and patients receiving a cardioplegia during heart surgery, we developed three
immunoenzymatic sandwich assays. The first assay involves the combination of two monoclonal **antibodies** (mAbs) specific for human **cTnI**. The second assay involves the combination of a mAb specific for **troponin C** (TnC) and an anti-**cTnI** mAb.
The third assay was a combination of a mAb specific for human cardiac troponin T (cTnT) and an anti-**cTnI** mAb. Fifteen serum samples from patients with AMI, 10 serum samples from patients receiving crystalloid cardioplegia during heart surgery, and 10 serum samples from patients receiving cold blood cardioplegia during heart surgery were assayed by the three two-site immunoassays. We confirmed that **cTnI** circulates not only in free form but also complexed with the other troponin components (TnC and cTnT). We showed that the predominant form in
blood is the **cTnI-TnC binary** complex (IC).
Free **cTnI**, the **cTnI**-cTnT **binary** complex, and
the cTnT-**cTnI-TnC** ternary complex were seldom present, and when present, were in small quantities compared with the binary complex IC. Similar results were obtained in both patient populations studied. These observations are essential for the development of new immunoassays with improved clinical sensitivity and for the selection of an appropriate **cTnI** primary calibrator.

AB The Ca2+ binding component (TnC) of troponin has been selectively labeled with either a spin label, N-(1-oxyl-2,2,6,6-tetramethyl-4-piperidinyl) iodoacetamide, or with a fluorescent **probe**, S-mercuric-N-dansyl cysteine, presumably at its single cysteine residue (Cys-98) in order to **probe** the interactions of TnC with divalent metals and with other subunits of troponin. The modified protein has the same Ca2+ binding properties as native TnC (Potter, J. D., and Gergely, J. (1975) J. Biol. Chem. 250, 4628), viz. two Ca2+ binding sites at which Mg2+ appears to compete (Ca2+-Mg2+ sites, KCa = 2 X 10(7) M-1) and two sites at which Mg2+ does not compete (Ca2+-specific sites, KCa = 2 X 10(5) M-1). Either Ca2+ or Mg2+ alters the ESR spectrum of spin-labeled TnC in a manner that indicates a decrease in the mobility of the label, Ca2+ having a slightly greater effect. In systems containing both Ca2+ and Mg2+ the mobility of the spin label is identical with that in systems containing Ca2+ alone. The binding constants for Ca2+ and Mg2+ deduced from ESR spectral changes are 10(7) and 10(3) M-1, respectively, and the apparent affinity for Ca2+ decreases by about an order of magnitude on adding 2 mM Mg2+. Thus, the ESR spectral change is associated with binding of Ca2+ to one or both of the Ca2+-Mg2+ sites. Addition of Ca2+ to the **binary** complexes of spin-labeled **TnC** with either troponin T (TnT) or troponin I (**TnI**) produces greater reduction in the mobility of the spin label than in the case of spin-labeled TnC alone, and in the case of the complex with **TnI** the affinity for Ca2+ is increased by an order of magnitude. The fluorescence of dansyl (5-dimethylaminonaphthalene-1-sulfonyl)-labeled TnC is enhanced by Ca2+ binding to both high and low affinity sites with apparent binding constants of 2.6 X 10(7) M-1 and 2.9 X 10(5) M-1, respectively, calculated from the transition midpoints. The presence of 2 mM Mg2+, which produces no effect on dansyl fluorescence itself, in contrast to its effect on the spin label, shifts the high affinity constant to 2 X 10(6) M-1. Spectral changes produced by Ca2+ binding to the TnC-**TnI** complex furnish evidence that the affinity of TnC for Ca2+ is increased in the complex. The reactivity of Cys-98 to the labels and to 5,5'-dithiobis(2-nitrobenzoic acid) (Nbs2) is decreased by Ca2+ or Mg2+ both with native TnC and in 6 M urea. The reaction rate between Cys-98 and Nbs2 decreases to one-half the maximal value at a Ca2+ concentration that suggests binding to the Ca2+-Mg2+ sites. Formation of a **binary** complex between **TnI** and **TnC** reduces the rate of reaction, and there is a further reduction

by Ca2+. The effect of Ca2+ takes place at concentrations that are 1 order
of magnitude lower than in the case of TnC alone. These results suggest that the Ca2+ binding site adjacent to Cys-98 is one of the Ca2+-Mg2+ binding sites.

AB . . . binding component (TnC) of troponin has been selectively labeled with either a spin label, N-(1-oxyl-2,2,6,6-tetramethyl-4-piperidinyl) iodoacetamide, or with a fluorescent **probe**, S-mercuric-N-dansyl cysteine, presumably at its single cysteine residue (Cys-98) in order to **probe** the interactions of TnC with divalent metals and with other subunits of troponin. The modified protein has the same Ca2+. . . change is associated with binding of Ca2+ to one or both of the Ca2+-Mg2+ sites. Addition of Ca2+ to the **binary** complexes of spin-labeled **TnC** with either troponin T (TnT) or troponin I (**TnI**) produces greater reduction in the mobility of the spin label than in the case of spin-labeled TnC alone, and in the case of the complex with **TnI** the affinity for Ca2+ is increased by an order of magnitude. AB We examined the release of cardiac troponin T (cTnT) and I (**cTnI**) into the blood of patients after acute myocardial infarction (AMI). Three postAMI serum samples were applied in separate analytical runs onto a calibrated gel filtration column (Sephacryl S-200), and the proteins were separated by molecular weight. Using commercial cTnT and **cTnI** assays measured on collected fractions, we found that troponin was released into blood as a ternary complex of cTnT-I-C, a binary **complex** of **cTnI**-C, and **free** cTnT, with no **free cTnI** within the limits of the analytical methodologies. The serum samples were also examined after incubation with EDTA and heparin. EDTA broke up troponin complexes into individual subunits, whereas heparin had no effect on the assays tested. We added **free** cTnC subunits to 24 AMI serum samples and found no marked increase in the total **cTnI** concentrations, using an immunoassay that gave higher values for the **cTnI**-C **complex** than **free cTnI**. To characterize the cross-reactivity of cTnT and **cTnI** assays, purified troponin standards in nine different forms were prepared, added to serum and plasma pools, and tested in nine quantitative commercial and pre-market assays for **cTnI** and one approved assay for cTnT. All nine **cTnI** assays recognized each of the troponin I forms (complexed and **free**). In five of these assays, the relative responses for **cTnI** were nearly equimolar. For the remainder, the response was substantially greater for **complexed cTnI** than for **free cTnI**.

Moreover, there was a substantial difference in the absolute concentration of results between **cTnI** assays. The commercial cTnT assay recognized binary and ternary complexes of troponin on a near equimolar basis. We conclude that all assays are useful for detection of cardiac injury. However, there are differences in absolute **cTnI** results due to a lack of mass standardization and heterogeneity in the cross-reactivities of **antibodies** to various troponin I forms.

AB Fourteen monoclonal **antibodies** (mAbs) against human cardiac troponin I (**cTnI**) were generated by commonly used experimental techniques. All these **antibodies**, as well as **antibody** 414 (HyTest), were specific for human **cTnI**. Fifteen **antibodies** thus obtained were tested in a sandwich **cTnI** immunofluorescence assay (altogether 196 combinations). Ten pairs giving the highest sensitivity were selected for further investigation. The effect of **TnI**-TnC **complex** formation on **antibody** interaction with antigen was analyzed. The formation of **TnI**-TnC **complex** results in a significant decrease of the interaction of mAbs with **TnI** for seven of 10 analyzed pairs of **antibodies**. Using two pairs of **cTnI**-specific mAbs, one that recognized only **free cTnI** but not **cTnI** **complexed** with cTnC, and another that could be used for measurement of total **cTnI** (**free cTnI** and **cTnI** in **complex** with cTnC), we demonstrated that the main part of **cTnI** in serum collected from acute myocardial infarction patients is presented in the complex from. We concluded that effective and reliable immunological detection of **TnI** is possible only when **antibodies** used for assay development recognize both **free TnI** and **TnI** **complexed** with other troponin components.

TI Troponin I is released in bloodstream of patients with acute myocardial infarction not in **free** form but as complex.

All these **antibodies**, as well as **antibody** 414 (HyTest), were specific for human **cTnI**. Fifteen **antibodies** thus obtained were tested in a sandwich **cTnI** immunofluorescence assay (altogether 196 combinations). Ten pairs giving the highest sensitivity were selected for further investigation. The effect of **TnI**-TnC **complex** formation on **antibody** interaction with antigen was analyzed. The formation of **TnI**-TnC **complex** results in a significant decrease of the interaction of mAbs with **TnI** for seven of 10 analyzed pairs of **antibodies**. Using two pairs of **cTnI**-specific mAbs, one that recognized only **free cTnI** but not **cTnI** **complexed** with cTnC, and another that could be used for

measurement of total **cTnI** (**free cTnI** and **cTnI** in **complex** with cTnC), we demonstrated that the main part of **cTnI** in serum collected from acute myocardial infarction patients is presented in the complex from. We concluded that effective and reliable immunological detection of **TnI** is possible only when **antibodies** used for assay development recognize both **free TnI** and **TnI complexed** with other troponin components.

AB Residues 89-100 of **troponin C** (C89-100) and 96-116 of troponin I (I96-116) interact with each other in the troponin complex (Dalgarno, D.C., Grand, R.J.A., Levine, B.A. Moir, A., J.G., Scott, G.M.M., and Perry, S.V. (1982) FEBS Lett. 150, 54-58) and are necessary for the Ca2+ sensitivity of actomyosin ATPase (Syska, H., Wilkinson, J.M., Grand, R.J.A., and Perry, S.V. (1976) Biochem. J. 153, 375-387 and Grabarek, Z., Drabikowski, W., Leavis, P.C., Rosenfeld, S.S., and Gergely, J. (1981) J. Biol. Chem. 256, 13121-13127). We have studied Ca2+-induced changes in the region C89-100 by monitoring the fluorescence of **troponin C** (TnC) labeled at Cys-98 with 5-(iodoacetamidoethyl)aminonaphthalene-1-sulfonic acid. Equilibrium titration of the labeled TnC with Ca2+ indicates that the **probe** is sensitive to binding to both classes of sites in **free** TnC as well as in its **complex** with **TnI**. When Mg2 X TnC is mixed with Ca2+ in a stopped flow apparatus, there is a rapid fluorescence increase related to Ca2+ binding to the unoccupied sites I and II followed by a slower increase (k = 9.9 s-1) that represents Mg2+-Ca2+ exchange at sites III and IV. In the TnC X **TnI complex**, the fast phase is much larger and the Mg2+-Ca2+ exchange at sites III and IV results in a small decrease rather than an increase in the fluorescence of the **probe**. The possibility is discussed that the fast change in the environment of Cys-98 upon Ca2+ binding to sites I and II may be instrumental in triggering activation of the thin filament by facilitating a contact between C89-100 and I96-116.

L9 ANSWER 4 OF 15 MEDLINE DUPLICATE 4
AB Troponin I (**TnI**) is the inhibitory component of the striated muscle Ca2+ regulatory protein troponin (Tn). The other two components of Tn are **troponin C** (TnC), the Ca2+-binding component, and troponin T (TnT), the tropomyosin-binding component. We have used limited chymotryptic digestion to **probe** the local conformation of **TnI** in the free state, the **binary TnC*** **TnI** complex, the ternary **TnC***. **TnI***TnT (Tn) complex, and in the reconstituted Tn*tropomyosin*F-actin filament. The digestion of **TnI** alone or in the TnC***TnI** complex produced initially two major fragments via a cleavage of the peptide bond between Phe100 and Asp101 in the so-called. . . digestion was slower in the absence than in the presence of Ca2+. These results indicate firstly that in both free **TnI** and **TnI** complexed with TnC there is an exposed and flexible site in the inhibitory region. Secondly, TnT affects the conformation of **TnI** in the inhibitory region and also in the region that contains the 140-141 bond. Thirdly, the 140-141 region of **TnI** is likely to interact with actin in the reconstituted thin filament when Ca2+ is absent. These findings are discussed in terms of the role of **TnI** in the mechanism of thin filament regulation, and in light of our previous results [Y. Luo, J.-L. Wu, J. Gergely, T. Tao, Biochemistry 36 (1997) 13449-13454] on the global conformation of **TnI**.

L9 ANSWER 5 OF 15 MEDLINE DUPLICATE 5

AB To determine the forms of cardiac troponin I (**cTnI**) circulating in the bloodstream of patients with acute myocardial infarction (AMI) and patients receiving a cardioplegia during heart surgery, we developed three immunoenzymatic sandwich assays. The first assay involves the combination of two monoclonal **antibodies** (mAbs) specific for human **cTnI**. The second assay involves the combination of a mAb specific for **troponin C** (TnC) and an anti-**cTnI** mAb. The third assay was a combination of a mAb specific for human cardiac troponin T (cTnT) and an anti-**cTnI** mAb. Fifteen serum samples from patients with AMI, 10 serum samples from patients receiving crystalloid cardioplegia during heart surgery, and. . . samples from patients receiving cold blood cardioplegia during heart surgery were assayed by the three two-site immunoassays. We confirmed that **cTnI** circulates not only in free form but also complexed with the other troponin components (TnC and cTnT). We showed that the predominant form in blood is the **cTnI**-**TnC** **binary** complex (IC). Free **cTnI**, the **cTnI**-cTnT **binary** complex, and the cTnT-**cTnI**-**TnC** ternary complex were seldom present, and when present, were in small quantities compared with the binary complex IC. Similar results. . . observations are essential for the development of new immunoassays with improved clinical sensitivity and for the selection of an appropriate **cTnI** primary calibrator.

AB Troponin I (**TnI**) is the inhibitory component of the striated muscle Ca2+ regulatory protein troponin (Tn). The other two components of Tn are **troponin C** (TnC), the Ca2+-binding component, and troponin T (TnT), the tropomyosin-binding component. We have used limited chymotryptic digestion to **probe** the local conformation of **TnI** in the free state, the **binary** **TnC*** **TnI** complex, the ternary **TnC***. **TnI***TnT (Tn) complex, and in the reconstituted Tn*tropomyosin*F-actin filament. The digestion of **TnI** alone or in the TnC***TnI** complex produced initially two major fragments via a cleavage of the peptide bond between Phe100 and Asp101 in the so-called inhibitory region. In the ternary Tn complex cleavage occurred at a new site between Leu140 and Lys141. In the absence of Ca2+ this was followed by digestion of the

fragment at Leu122 and Met116. In the reconstituted thin filament the same
fragments as in the case of the ternary complex were produced, but the rate of digestion was slower in the absence than in the presence of Ca2+. These results indicate firstly that in both free **TnI** and **TnI** complexed with TnC there is an exposed and flexible site in the inhibitory region. Secondly, TnT affects the conformation of **TnI** in the inhibitory region and also in the region that contains the 140-141 bond. Thirdly, the 140-141 region of **TnI** is likely to interact with actin in the reconstituted thin filament when Ca2+ is absent. L9 ANSWER 8 OF 15 EMBASE COPYRIGHT 2001 ELSEVIER SCI. B.V.DUPLICATE 8
AB Differences in pH sensitivity of tension generation between developing and
adult cardiac myofilaments, which contain the same isoform of **troponin C** (TnC)(i) have been proposed to be due to troponin I (**TnI**) isoform switching from the slow Skeletal (ss) to cardiac (c) **TnI** isoforms (21). We investigated the effects of acidic pH on Ca2+-activation of force in chemically skinned preparations of adult rat. . . shift in pCa50 in soleus fibers did not change with sarcomere length. Troponin subunit interactions were also investigated, using cardiac **troponin C** (cTnC(IA)) labeled with a fluorescent **probe**, 2-(4'-iodoacetamidoanilino)-naphthalene-6-sulfonic acid. Under acidic conditions, cTnC(IA) demonstrated a decrease in Ca2+affinity. This decrease was amplified both in the **binary** complex **cTnC**(IA)-**cTnI** and in the complex cTnC(IA)-**cTnI**-cTnT-tropomyosin to the same extent. In contrast, substitution of ssTnI for **cTnI** in these complexes produced the same decrease in Ca2+ affinity in response to acidic pH as cTnC(IA) alone.
These results. . . on tension generation and Ca2+ sensitivity between soleus fibers and trabeculae are due to the presence of different isoforms of **TnI**.

L9 ANSWER 10 OF 15 MEDLINE DUPLICATE 9
AB NMR spectroscopy and selective isotope labeling of both recombinant cardiac **troponin C** (cTnC3) and a truncated cardiac troponin I (**cTnI**/NH2) lacking the N-terminal 32-amino acid cardiac-specific sequence have been used to **probe** protein-protein interactions central to muscle contraction. Using [methyl-13C]Met-labeled cTnC3, all 10 cTnC Met residues of Ca(2+)-saturated cTnC3 could be resolved in the two-dimensional heteronuclear single- and multiple-quantum coherence spectrum of the **cTnI**.cTnC complex. Based on the known Met assignments in cTnC3, the largest chemical shift changes were observed for Met81, Met120, Met137,. . . terminus of the central helix. Minimal chemical shift changes were observed for Met45, Met47, and Met103 of cTnC3 in the **cTnI**.cTnC complex. All 6 Met residues in [methyl13C]Met-labeled

cTnI/NH2 could be resolved in the **cTnI**.cTnC complex, suggesting that both **cTnI** and **cTnC** form a stable homogeneous **binary** complex under the conditions of the NMR experiment. In the absence of added protease inhibitors in the **cTnI**.cTnC complex, **cTnI**/NH2 was found to undergo selective proteolysis to yield a 5.5-kDa N-terminal fragment corresponding to residues 33-80. Judging from the NMR spectra of [methyl13C]Met-labeled cTnC3, **cTnI**-(33-80) was sufficient for interaction with the C-terminal domain of cTnC in a manner identical to that observed for native **cTnI**/NH2. However, in the presence of the proteolytic fragment **cTnI**-(33-80), the chemical shift of Met81 was not perturbed from its position in free cTnC3. Thus, residues located C-terminal to Arg80 in **cTnI** appear to be responsible for interaction with the N-terminal half of cTnC. Taken together, these results provide strong evidence for an antiparallel arrangement for the two proteins in the troponin complex such that the N-terminal portion of **cTnI** interacts with the C-terminal domain of cTnC. This interaction likely plays a role in maintaining the stability of the **TnI**.TnC complex.

L9 ANSWER 11 OF 15 SCISEARCH COPYRIGHT 2001 ISI (R)
TI MODULATION OF **TROPONIN-C** BINDING TO TROPONIN-T BY CA2+, **PROBED** BY FLUORESCENCE
AB The effects of Ca2+ on the binding interaction between **troponin -C** (TnC) and troponin-T (TnT) and between TnC and troponin-I (**TnI**) were studied in both the binary complexes and the presence of

other subunits and tropomyosin (Tm). Rabbit skeletal TnC was. . .
Adding Tm to the system weakened the binding of TnT to TnC by at least 50 - 60 percent. Adding **TnI** to DACM-TnC alone also enhanced the fluorescence (20-22%). An affinity constant 10(8) M-1 for **TnC-TnI binary** complex was obtained. If Tn-I and the labeled TnC were premixed first in 1:1 stoichiometry, then titrated with TnT, a further fluorescence increase (34%) similar to that in the absence of **TnI** was observed. The fit of the binding curve shows that K(a) of TnT to TnC increased (1.5 x 10(6) M-1). When **TnI** was added to the TnC-TnT complex at the end of titration when the fluorescence binding curve became leveled, quenching (12%) occurred. The latter result indicates that **TnI** competes with TnT for the same binding sites on TnC. As binding of TnC is at least 100 times as strong to **TnI** as to TnT, a quenching effect is observed. Furthermore, the conformation of **TnC** in the **TnC-TnI binary** complex may vary from that of TnC alone; binding of TnT to TnC is greatly enhanced (directly or indirectly by **TnI**) in the TnC-**TnI** complex. These results indicate that the variation of binding affinity between TnC and TnT as modulated by Ca2+ may play. . .

L9 ANSWER 14 OF 15 MEDLINE DUPLICATE 12
AB We have determined six molecular distances among four sites in the **binary** complex formed between **troponin C** (**TnC**) and troponin I (**TnI**) by fluorescence resonance energy transfer between donor and acceptor **probes** that were either an intrinsic fluorophore (Trp158 of **TnI**) or extrinsic **probes** attached to the sites. The three extrinsic **probes** were dansylaziridine (DNZ), N'-(iodoacetyl)-N'-(8-sulfo-1-naphthyl)ethylenediamine (IAEDANS) and 5-(iodoacetamido)eosin (IAE). The four fluorophores provided four donor-acceptor pairs: DNZ----IAE, Trp----IAEDANS, IAEDANS----IAE, and Trp----DNZ.. . . from measurements of energy transfer from (1) Met25 (DNZ) to Cys98 (IAE) in TnC, (2) Trp158 to Cys133 (IAEDANS) in **TnI**, (3) Cys98 (IAEDANS) of TnC to Cys133(IAE) of **TnI**, (4) Trp158 of **TnI** to Cys98(IAEDANS) of TnC, and (6) Met25(DNZ) of TnC to Cys133(IAE) of **TnI**. Distance (1) in TnC was little affected when the isolated protein was complexed with **TnI**, whereas distance (2) in **TnI** increased by 6A (29%) when **TnI** was incorporated into the binary complex. In the presence of EGTA, the six donor-acceptor separations (R) in the complex were. . .

L9 ANSWER 15 OF 15 MEDLINE DUPLICATE 13
AB . . . binding component (TnC) of troponin has been selectively labeled with either a spin label, N-(1-oxyl-2,2,6,6-tetramethyl-4-piperidinyl) iodoacetamide, or with a fluorescent **probe**, S-mercuric-N-dansyl cysteine, presumably at its single cysteine residue (Cys-98) in order to **probe** the interactions of TnC with divalent metals and with other subunits of troponin. The modified protein has the same Ca2+. . . change is associated with binding of Ca2+ to one or both of the Ca2+-Mg2+ sites. Addition of Ca2+ to the **binary** complexes of spin-labeled **TnC** with either troponin T (TnT) or troponin I (**TnI**) produces greater reduction in the mobility of the spin label than in the case of spin-labeled TnC alone, and in the case of the complex with **TnI** the affinity for Ca2+ is increased by an order of magnitude. The fluorescence of dansyl (5-dimethylaminonaphthalene-1-sulfonyl)-labeled TnC is enhanced by. . . spin label, shifts the high affinity constant to 2 X 10(6) M-1. Spectral changes produced by Ca2+ binding to the TnC-**TnI** complex furnish evidence that the affinity of TnC for Ca2+ is increased in the complex. The reactivity of Cys-98 to. . . decreases to one-half the maximal value at a Ca2+ concentration that suggests binding to the Ca2+-Mg2+ sites. Formation of a **binary** complex between **TnI** and **TnC** reduces the rate of reaction, and there is a further reduction by Ca2+. The effect of Ca2+ takes place at. . .

AB The Ca2+ binding component (TnC) of troponin has been selectively labeled with either a spin label, N-(1-oxyl-2,2,6,6-tetramethyl-4-piperidinyl) iodoacetamide, or with a fluorescent **probe**, S-mercuric-N-dansyl cysteine, presumably at its single cysteine residue (Cys-98) in order to **probe** the interactions of TnC with divalent metals and with other subunits of troponin. The modified protein has the same Ca2+ binding properties as native TnC (Potter, J. D., and Gergely, J. (1975) J. Biol. Chem. 250, 4628), viz. two Ca2+ binding sites at which Mg2+ appears to compete (Ca2+-Mg2+ sites, KCa = 2 X 10(7) M-1) and two sites at which Mg2+ does not compete (Ca2+-specific sites, KCa = 2 X 10(5) M-1). Either Ca2+ or Mg2+ alters the ESR spectrum of spin-labeled TnC in a manner that indicates a decrease in the mobility of the label, Ca2+ having a slightly greater effect. In systems containing both Ca2+ and Mg2+ the mobility of the spin label is identical with that in systems containing Ca2+ alone. The binding constants for Ca2+ and Mg2+ deduced from ESR spectral changes are 10(7) and 10(3) M-1, respectively, and the apparent affinity for Ca2+ decreases by about an order of magnitude on adding 2 mM Mg2+. Thus, the ESR spectral change is associated with binding of Ca2+ to one or both of the Ca2+-Mg2+ sites. Addition of Ca2+ to the **binary** complexes of spin-labeled **TnC** with either troponin T (TnT) or troponin I (**TnI**) produces greater reduction in the mobility of the spin label than in the case of spin-labeled TnC alone, and in the case of the complex with **TnI** the affinity for Ca2+ is increased by an order of magnitude. The fluorescence of dansyl (5-dimethylaminonaphthalene-1-sulfonyl)-labeled TnC is enhanced by Ca2+ binding to both high and low affinity sites with apparent binding constants of 2.6 X 10(7) M-1 and 2.9 X 10(5) M-1, respectively, calculated from the transition midpoints. The presence of 2 mM Mg2+, which produces no effect on dansyl fluorescence itself, in contrast to its effect on the spin label, shifts the high affinity constant to 2 X 10(6) M-1. Spectral changes produced by Ca2+ binding to the TnC-**TnI** complex furnish evidence that the affinity of TnC for Ca2+ is increased in the complex. The reactivity of Cys-98 to the labels and to 5,5'-dithiobis(2-nitrobenzoic acid) (Nbs2) is decreased by Ca2+ or Mg2+ both with native TnC and in 6 M urea. The reaction rate between Cys-98 and Nbs2 decreases to one-half the maximal value at a Ca2+ concentration that suggests binding to the Ca2+-Mg2+ sites. Formation of a **binary** complex between **TnI** and **TnC** reduces the rate of reaction, and there is a further reduction by Ca2+. The effect of Ca2+ takes place at concentrations that are 1 order of magnitude lower than in the case of TnC alone. These results suggest

that the Ca2+ binding site adjacent to Cys-98 is one of the Ca2+-Mg2+ binding sites.

AB . . . binding component (TnC) of troponin has been selectively labeled with either a spin label, N-(1-oxyl-2,2,6,6-tetramethyl-4-piperidinyl) iodoacetamide, or with a fluorescent **probe**, S-mercuric-N-dansyl cysteine, presumably at its single cysteine residue (Cys-98) in order to **probe** the interactions of TnC with divalent metals and with other subunits of troponin. The modified protein has the same Ca2+. . . change is associated with binding of Ca2+ to one or both of the Ca2+-Mg2+ sites. Addition of Ca2+ to the **binary** complexes of spin-labeled **TnC** with either troponin T (TnT) or troponin I (**TnI**) produces greater reduction in the mobility of the spin label than in the case of spin-labeled TnC alone, and in the case of the complex with **TnI** the affinity for Ca2+ is increased by an order of magnitude. AB Troponin I (**TnI**) is the inhibitory component of the striated muscle Ca2+ regulatory protein troponin (Tn). The other two components of

Tn are **troponin C** (TnC), the Ca2+-binding component, and troponin T (TnT), the tropomyosin-binding component. We have used limited chymotryptic digestion to **probe** the local conformation of **TnI** in the free state, the binary **TnC*TnI** complex, the **ternary TnC*. TnI*TnT** (Tn) complex, and in the reconstituted Tn*tropomyosin*F-actin filament. The digestion of **TnI** alone or in the TnC*TnI complex produced initially two major fragments via a cleavage of the peptide bond between Phe100 and Asp101 in the so-called inhibitory region. In the ternary Tn complex cleavage occurred at a new site between Leu140 and Lys141. In the absence of Ca2+ this was followed by digestion of the 1-140 fragment at Leu122 and Met116. In the reconstituted thin filament the same fragments as in the case of the ternary complex were produced, but the rate of digestion was slower in the absence than in the presence of Ca2+. These results indicate firstly that in both free **TnI** and **TnI** complexed with TnC there is an exposed and flexible site in the inhibitory region. Secondly, TnT affects the conformation of **TnI** in the inhibitory region and also in the region that contains the 140-141 bond. Thirdly, the 140-141 region of **TnI** is likely to interact with actin in the reconstituted thin filament when Ca2+ is absent. These findings are discussed in terms of the role of **TnI** in the mechanism of thin filament regulation, and in light of our previous results [Y. Luo, J.-L. Wu, J. Gergely, T. Tao, Biochemistry 36 (1997) 13449-13454] on the global conformation of **TnI**.

AB To determine the forms of cardiac troponin I (**cTnI**) circulating in the bloodstream of patients with acute myocardial infarction (AMI) and patients receiving a cardioplegia during heart surgery, we developed three immunoenzymatic sandwich assays. The first assay involves the combination of two monoclonal **antibodies** (mAbs) specific for human **cTnI**. The second assay involves the combination of a mAb specific for **troponin C** (TnC) and an anti-**cTnI** mAb. The third assay was a combination of a mAb specific for human cardiac troponin T (cTnT) and an anti-**cTnI** mAb. Fifteen serum samples from patients with AMI, 10 serum samples from patients receiving crystalloid cardioplegia during heart surgery, and 10 serum samples from patients receiving cold blood cardioplegia during heart surgery were assayed by the three two-site immunoassays. We confirmed that **cTnI** circulates not only in free form but also complexed with the other troponin components (TnC and cTnT). We showed that the predominant form in blood is the **cTnI**-TnC binary complex (IC). Free **cTnI**, the **cTnI-cTnT** binary complex, and the **cTnT-cTnI-TnC ternary** complex were seldom present, and when present, were in small quantities compared with the binary complex IC. Similar results were obtained in both patient populations studied. These observations are essential for the development of new immunoassays with improved clinical sensitivity and for the selection of an appropriate **cTnI** primary calibrator.

AB Fluorescence lifetime and acrylamide quenching studies were carried out to characterize the interactions between the subunits of troponin under various conditions of metal ion binding. **Troponin C** was labeled at Cys-98 with N-(iodoacetyl)-N'-(5-sulfo-1-naphthyl)ethylenediamine. In the presence of Ca2+, the fluorescence decay of labeled **troponin C** (TnC*) was monoexponential, lifetime tau = 15.5 ns and quenching rate constant kq = 2.97 X 10(8) M-1 s-1. In the absence of Ca2+, the decay was resolvable into a major component with tau = 11.9 ns and a minor component with tau = 20.5 ns, with corresponding values of kq = 4.80 X 10(8) and 0.66 X 10(8) M-1 s-1, respectively. Upon the binding of either troponin I (**TnI**) or troponin T (TnT) in the presence of Ca2+, tau increased to approximately 18 ns, and kq decreased to approximately 0.8 X 10(8) M-1 s-1. For the Ca2+ form of the **TnC*-TnI-TnT ternary** complex, values of tau = 17.6 ns and kq = 1.73 X 10(8) M-1 s-1 were obtained. These values did not vary significantly when Ca2+ was removed, or when Mg2+ replaced Ca2+. These findings were interpreted as follows: the region around Cys-98 of TnC* adopts a looser conformation upon the removal of Ca2+ from the high-affinity sites. Both **TnI** and TnT bind to TnC* in the region containing Cys-98. The **probe** is shielded from the solvent to a greater extent in the binary complexes than in the ternary complex.(ABSTRACT TRUNCATED AT 250 WORDS)

AB . . . studies were carried out to characterize the interactions between the subunits of troponin under various conditions of metal ion binding. **Troponin C** was labeled at Cys-98 with N-(iodoacetyl)-N'-(5-sulfo-1-naphthyl)ethylenediamine. AB We examined the release of cardiac troponin T (cTnT) and I (**cTnI**) into the blood of patients after acute myocardial infarction (AMI). Three postAMI serum samples were applied in separate analytical runs onto a calibrated gel filtration column (Sephacryl S-200), and the proteins were separated by molecular weight. Using commercial cTnT and **cTnI** assays measured on collected fractions, we found that troponin was released into blood as a ternary complex of cTnT-I-C, a binary **complex** of **cTnI**-C, and **free** cTnT, with no **free cTnI** within the limits of the analytical methodologies. The serum samples were also examined after incubation with EDTA and heparin. EDTA broke up troponin complexes into individual subunits, whereas heparin had no effect on the assays tested. We added **free** cTnC subunits to 24 AMI serum samples and found no marked increase in the total **cTnI** concentrations, using an immunoassay that gave higher values for the **cTnI**-C **complex** than **free cTnI**. To characterize the cross-reactivity of cTnT and **cTnI** assays, purified troponin standards in nine different forms were prepared, added to serum and plasma pools, and tested in nine quantitative commercial and pre-market assays for **cTnI** and one approved assay for cTnT. All nine **cTnI** assays recognized each of the troponin I forms (complexed and **free**). In five of these assays, the relative responses for **cTnI** were nearly equimolar. For the remainder, the response was substantially greater for **complexed cTnI** than for **free cTnI**.
Moreover, there was a substantial difference in the absolute concentration of results between **cTnI** assays. The commercial cTnT assay recognized binary and ternary complexes of troponin on a near equimolar basis. We conclude that all assays are useful for detection of cardiac injury. However, there are differences in absolute **cTnI** results due to a lack of mass standardization and heterogeneity in the cross-reactivities of **antibodies** to various troponin I forms.

AB Troponin (Tn), the **complex** of three subunits (TnC, **TnI** , and TnT), plays a key role in Ca2+ dependent regulation of muscle contraction. To elucidate the interactions between the Tn subunits and the conformation of TnC in the Tn complex, we have determined the crystal structure of TnC in **complex** with the N-terminal fragment of **TnI** (TnI1-47). The structure was solved by single isomorphous replacement method in combination with multiple wavelength anomalous dispersion data. The refinement converged to a crystallographic R-factor of 22.2% (R-**free** = 32.6%). The central, connecting alpha-helix observed in the structure of **uncomplexed** TnC (TnCfree) is unwound at the center and bent by 90 degrees. As a result, the TnC in the complex has a compact globular shape with direct interactions between the N- and C-lobes, in contrast to the elongated dumb-bell shaped molecule of **uncomplexed** TnC. The 31-residue long TnI1-47 alpha-helix stretches on the surface of TnC and stabilizes its compact conformation by multiple contacts with both TnC lobes. The amphiphilic C-terminal end of the TnI1-47 alpha-helix is tightly bound in the hydrophobic pocket of the TnC C-lobe through 38 van der Waals interactions. The results indicate the major difference between integrated (TnC) and isolated (calmodulin) Ca2+ **receptors**. The TnC/TnI1-47 structure suggests the model for a novel regulatory **TnI** segment **bound** to TnC and implies the mechanism of how Tn regulates the muscle contraction.

TI The crystal structure of **troponin C** in **complex** with N-terminal fragment of troponin I. The mechanism of how the inhibitory action of troponin I is released by Ca(2+)-binding. . .

AB Fourteen monoclonal **antibodies** (mAbs) against human cardiac troponin I (**cTnI**) were generated by commonly used experimental techniques. All these **antibodies**, as well as **antibody** 414 (HyTest), were specific for human **cTnI**. Fifteen **antibodies** thus obtained were tested in a sandwich **cTnI** immunofluorescence assay (altogether 196 combinations). Ten pairs giving the highest sensitivity were selected for further investigation. The effect of **TnI**-TnC **complex** formation on **antibody** interaction with antigen was analyzed. The formation of **TnI**-TnC **complex** results in a significant decrease of the interaction of mAbs with **TnI** for seven of 10 analyzed pairs of **antibodies**. Using two pairs of **cTnI**-specific mAbs, one that recognized only **free cTnI** but not **cTnI** **complexed** with cTnC, and another that could be used for measurement of total **cTnI** (**free cTnI** and **cTnI** in **complex** with cTnC), we demonstrated that the main part of **cTnI** in serum collected from acute myocardial infarction patients is presented in the complex from. We concluded that effective and reliable immunological detection of **TnI** is possible only when **antibodies** used for assay development recognize both **free TnI** and **TnI** **complexed** with other troponin components.

AB NMR spectroscopy and selective isotope labeling of both recombinant cardiac **troponin C** (cTnC3) and a truncated cardiac troponin I (**cTnI**/NH2) lacking the N-terminal 32-amino acid cardiac-specific sequence have been used to **probe** protein-protein interactions central to muscle contraction. Using [methyl-13C]Met-labeled cTnC3, all 10 cTnC Met residues of

Ca(2+)-saturated cTnC3 could be resolved in the two-dimensional heteronuclear single- and multiple-quantum coherence spectrum of the **cTnI**.cTnC **complex**. Based on the known Met assignments in cTnC3, the largest chemical shift changes were observed for Met81, Met120, Met137, and Met157. Methionines 120, 137, and 157 are all located in the C-terminal domain of cTnC. Methionine 81 is located at the N terminus of the central helix. Minimal chemical shift changes were observed for Met45, Met47, and Met103 of cTnC3 in the **cTnI**.cTnC **complex**. All 6 Met residues in [methyl13C]Met-labeled **cTnI**/NH2 could be resolved in the **cTnI**.cTnC **complex**, suggesting that both **cTnI** and cTnC form a stable homogeneous binary complex under the conditions of the NMR experiment. In the absence of added protease inhibitors in the **cTnI**.cTnC **complex**, **cTnI**/NH2 was found to undergo selective proteolysis to yield a 5.5-kDa N-terminal fragment corresponding to residues 33-80. Judging from the NMR spectra of [methyl13C]Met-labeled cTnC3, **cTnI**-(33-80) was sufficient for interaction with the C-terminal domain of cTnC in a manner identical to that observed for native **cTnI**/NH2. However, in the presence of the proteolytic fragment **cTnI**-(33-80), the chemical shift of Met81 was not perturbed from its position in **free** cTnC3. Thus, residues located C-terminal to Arg80 in **cTnI** appear to be responsible for interaction with the N-terminal half of cTnC. Taken together, these results provide strong evidence for an antiparallel arrangement for the two proteins in the troponin complex such that the N-terminal portion of **cTnI** interacts with the C-terminal domain of cTnC. This interaction likely plays a role in maintaining the stability of the **TnI**.TnC **complex**.

TI NMR studies delineating spatial relationships within the cardiac troponin I-**troponin C complex**.

AB NMR spectroscopy and selective isotope labeling of both recombinant cardiac **troponin C** (cTnC3) and a truncated cardiac troponin I (**cTnI**/NH2) lacking the N-terminal 32-amino acid cardiac-specific sequence have been used to **probe** protein-protein interactions central to muscle contraction. Based on the known Met assignments in cTnC3, the largest chemical shift changes were observed for Met81, Met120, Met137, and. . . terminus of the central helix. Minimal chemical shift changes were observed for Met45, Met47, and Met103 of cTnC3 in the **cTnI**.cTnC **complex**. All 6 Met residues in [methyl13C]Met-labeled **cTnI**/NH2 could be resolved in the **cTnI**.cTnC **complex**, suggesting that both **cTnI** and cTnC form a stable homogeneous binary complex under the conditions of the NMR experiment. In the absence of added protease inhibitors in the **cTnI**.cTnC **complex**, **cTnI**/NH2 was found to undergo selective proteolysis to yield a 5.5-kDa N-terminal fragment corresponding to residues 33-80. Judging from the NMR spectra of [methyl13C]Met-labeled cTnC3, **cTnI**-(33-80) was sufficient for interaction with the C-terminal domain of cTnC in a manner identical to that observed for native **cTnI**/NH2. However, in the presence of the proteolytic fragment **cTnI**-(33-80), the chemical shift of Met81 was not perturbed from its position in **free** cTnC3. Thus, residues located C-terminal to Arg80 in **cTnI** appear to be responsible for interaction with the N-terminal half of cTnC. Taken together, these results provide strong evidence for an antiparallel arrangement for the two proteins in the troponin complex such that the N-terminal portion of **cTnI** interacts with the C-terminal domain of cTnC. This interaction likely plays a role in maintaining the stability

of the **TnI**.TnC **complex**.

AB The interaction of troponin I (**CTnI**) with **troponin C** (CTnC) from bovine cardiac muscle was studied using CTnC modified at Cys35 and Cys84 with the fluorescent **probe** 2-[(4'-iodoacetamido)-anilino]naphthalene-6-sulfonic acid (CTnCIAANS). The association constant for complex formation between the two proteins was determined at 20 degrees C in 0.4 M KCl, 1 mM DTT, 1 mM EGTA, and 25 mM MOPS, pH 7.2. In the presence of EGTA, Mg2+, and Ca2+ these constants were 1.46 x 10(7), 4.1 x 10(7), and 12.7 x 10(7) M-1, respectively, with corresponding **free** energy values of -9.62, -10.23, and -10.88 kcal mol-1. The **CTnI**-CTnCIAANS **complex** was stabilized by -0.61 kcal when the two Ca/Mg sites of CTnCIAANS were saturated with Mg2+ and by -1.26 kcal when all three Ca2+ sites were occupied by Ca2+. These results suggest that calcium activation in cardiac muscle may be accompanied by a coupling **free** energy of -0.65 kcal. This value is a factor of 4 smaller than the value previously determined, using a similar method, for the (troponin I).(**troponin C**) **complex** from skeletal muscle [Wang, C.-K., & Cheung, H.C. (1985) Biophys. J.48, 727-739]. Since CTnC has only one Ca(2+)-specific site and **troponin C** from skeletal muscle has two such sites, the present result is a factor of 2 smaller than that for the skeletal complex on the basis of a single specific site. Phosphorylation of **CTnI** by 3',5'-cyclic AMP-dependent protein kinase resulted in a decrease of the association constants by a factor of 2.5-3.5.(ABSTRACT TRUNCATED AT 250 WORDS)

AB Inhibition of muscle force development by acidic pH is a well known phenomenon, yet the exact mechanism by which a decrease in pH inhibits the Ca2+-activated force in striated myofilaments remains poorly understood. Whether or not the deactivation by acidic pH involves direct competition between Ca2+ and protons for regulatory binding sites on fast skeletal **troponin C** (TnC) or whether other proteins in thin filament regulation are important remains unclear. We measured the effects of acidic pH on Ca2+-dependent fluorescent changes in TnC labeled with the **probe** danzylaziridine (Danz), which reports Ca2+ binding to the regulatory (Ca2+-specific) sites. Measurements were also made with TnCDanz **complexed** with the inhibitory Tn unit, **TnI**, and in the whole Tn **complex**. Our results show that a drop in pH from 7.0 to 6.5 is associated with a 1.6-fold increase in the midpoint for the relation between **free** Ca2+ and Ca2+ binding to the regulatory sites on TnCDanz. However, when TnCDanz was present in its **complex** with either **TnI** alone or with **TnI**-TnT, the increase in midpoint **free** Ca2+ was increased by 3.5-fold. We tested whether this potentiation in the effect of acidic pH on Ca2+ binding to TnC is due to a pH-induced alteration in the binding of **TnI** to TnC. A decrease in pH from 7.0 to 6.5 was associated with a halving of the affinity of **TnI** for TnC. We also **probed** the effect of acidic pH on **TnI**. This was done (i) by measuring the intrinsic fluorescence of tryptophan residues in **TnI** alone and (ii) by measuring fluorescence of **TnI** (in the Tn **complex**) labeled at Cys-133 with 5-iodoacetamidofluorescein. A drop in pH from 7.0 to 6.5 was associated with a 15% decrease in intrinsic fluorescence and with a 30% decrease in the fluorescence of the 5-iodoacetamidofluorescein **probe**. We conclude, therefore, that while protons and Ca2+ may directly affect Ca2+ binding to regulatory sites on fast skeletal TnC, the

effect of acidic pH on TnC Ca2+ binding is amplified in the **TnI**
-TnC and Tn **complexes** by a pH-related effect on the affinity of
TnI for TnC.

AB We have determined the **free** energy of formation of the binary **complexes** formed between skeletal **troponin C** and troponin T (TnC.TnT) and between troponin T and troponin I (TnT. **TnI**). This was accomplished by using TnC fluorescently modified at Cys-98 with N-(iodoacetyl)-N'-(5-sulfo-1-naphthyl)ethylenediamine for the first **complex** and **TnI** labeled at Cys-133 with the same **probe** for the other complex. The **free** energy of the ternary **complex** formed between **troponin C** and the binary **complex** TnT.**TnI** [TnC.(TnT.**TnI**

)] was also measured by monitoring the emission of 5-(iodoacetamido)eosin attached to Cys-133 of the troponin I in TnT.**TnI**. The **free** energies were -9.0 kcal.mol-1 for TnC.TnT, -9.2 kcal.mol-1 for TnT.**TnI**, and -8.7 kcal.mol-1 for TnC.(TnT.**TnI**). In the presence of Mg2+ the **free** energies of TnC.TnT and TnC.(TnT.**TnI**) were -10.3 and -10.9 kcal.mol-1, respectively; in the presence of Ca2+ the corresponding **free** energies were -10.6 and -13.5 kcal.mol-1. Mg2+ and Ca2+ had negligible effect on the **free** energy of TnT.**TnI**. From these results the **free** energies of the formation of troponin from the three subunits were found to be -16.8 kcal.mol-1, -18.9 kcal.mol-1, and -21.6 kcal.mol-1 in the presence of EGTA, Mg2+, and Ca2+, respectively. Most of the **free** energy decrease caused by Ca2+ binding to the Ca2+-specific sites is derived from stabilization of the **TnI**-TnC linkage.(ABSTRACT TRUNCATED AT 250 WORDS)

AB Residues 89-100 of **troponin C** (C89-100) and 96-116 of

troponin I (I96-116) interact with each other in the troponin complex (Dalgarno, D.C., Grand, R.J.A., Levine, B.A. Moir, A., J.G., Scott, G.M.M., and Perry, S.V. (1982) FEBS Lett. 150, 54-58) and are necessary for the Ca2+ sensitivity of actomyosin ATPase (Syska, H., Wilkinson, J.M., Grand, R.J.A., and Perry, S.V. (1976) Biochem. J. 153, 375-387 and Grabarek, Z., Drabikowski, W., Leavis, P.C., Rosenfeld, S.S., and Gergely, J. (1981) J. Biol. Chem. 256, 13121-13127). We have studied Ca2+-induced changes in the region C89-100 by monitoring the fluorescence of **troponin C** (TnC) labeled at Cys-98 with 5-(iodoacetamidoethyl)aminonaphthalene-1-sulfonic acid. Equilibrium titration of the labeled TnC with Ca2+ indicates that the **probe** is sensitive to binding to both classes of sites in **free** TnC as well as in its **complex** with **TnI**. When Mg2 X TnC is mixed with Ca2+ in a stopped flow apparatus, there is a rapid fluorescence increase related to Ca2+ binding to the unoccupied sites I and II followed by a slower increase (k = 9.9 s-1) that represents Mg2+-Ca2+ exchange at sites III and IV. In the TnC X **TnI complex**, the fast phase is much larger and the Mg2+-Ca2+ exchange at sites III and IV results in a small decrease rather than an increase in the fluorescence of the **probe**. The possibility is discussed that the fast change in the environment of Cys-98 upon Ca2+ binding to sites I and II may be instrumental in triggering activation of the thin filament by facilitating a contact between C89-100 and I96-116.

AB We report that bepridil, a Ca++ channel blocker and calmodulin antagonist, which has been shown to enter myocytes, stimulates the mechanical and biochemical activity of cardiac myofilaments. Bepridil increased significantly the level of Ca++-dependent actomyosin Mg++-ATPase activity of myofibrils and the submaximal force developed by chemically skinned trabeculae of pig heart. In the range of concentrations (10-100 microM) in which bepridil showed this stimulatory activity, diltiazem and verapamil were without effect. The effect of bepridil on myofilament force and ATPase activity was higher at relatively low **free** Ca++ concentrations, and myofibrils lacking troponin-tropomyosin were not affected by bepridil. Associated with the stimulation of force and ATPase activity by bepridil was an increase in the amounts of Ca++ **bound** to **troponin C** (TnC). That bepridil stimulates TnC Ca++ binding was also shown in experiments using pure TnC labeled with 2-(4'-iodoacetamidoanilo)naphthalene-6-sulfonic acid, a fluorescent **probe** that reports Ca++ bound to the single "regulatory" site. Effects of bepridil on the fluorescence of a felodipine-cardiac TnC complex indicate that bepridil binds to TnC over the same range of doses where it affects myofilament activity. Our results indicate that the inotropic action of bepridil may result from a net response of heart cells to influences on the delivery of Ca++ to the myofilaments and their response to Ca++.

AB We determined the **free** energy of interaction between rabbit skeletal troponin I (**TNI**) and **troponin C** (TNC) at 10 degrees and 20 degrees C with fluorescently labeled proteins. The sulfhydryl **probe** 5-iodoacetamidoeosin (IAE) was attached to cysteine (Cys)-98 of TNC and to Cys-133 of **TNI**, and each of the labeled proteins was titrated with the other unlabeled protein. The association constant for formation of the **complex** between labeled TNC (TNC*) and **TNI** was 6.67 X 10(5) M-1 in 0.3 M KCl, and pH 7.5 at 20 degrees C. In the presence of bound Mg2+, the binding constant increased to 4.58 X 10(7) M-1 and in the presence of excess of Ca2+, the association constant was 5.58 X 10(9) M-1. Very similar association constants were obtained when labeled **TNI** was titrated with unlabeled TNC. The energetics of Ca2+ binding to TNC* and the **complex TNI** X TNC* were also determined at 20 degrees C. The two sets of results were used to separately determine the coupling **free** energy for binding **TNI** and Mg2+, or Ca2+ to TNC. The results yielded a total coupling **free** energy of -5.4 kcal. This **free** energy appeared evenly partitioned into the two species: **TNI** X TNC(Mg)2 or **TNI** X TNC(Ca)2, and **TNI** X TNC(Ca)4. The first two species were each stabilized by -2.6 kcal, with respect to the Ca2+ **free TNI** X TNC **complex**, and **TNI** X TNC(Ca)4 was stabilized by -2.8 kcal, respect to **TNI** X TNC(Ca)2 or **TNI** X TNC(Mg)2. The coupling **free** energy was shown to produce cooperatively **complexes** formed between **TNI** and TNC in which the high affinity sites were initially saturated as a function of **free** Ca2+ to yield **TNI** X TNC(Ca)4. This saturation occurred in the **free** Ca2+ concentration range 10(-7) to 10(-5) M. The cooperative strengthening of the linkage between **TNI** and TNC induced by Ca2+ binding to the Ca2+-specific sites of TNC may have a direct relationship to activation of actomyosin ATPase. The nature of the forces involved in the Ca2+-induced strengthening of the complex is discussed.

AB We determined the **free** energy of interaction between rabbit skeletal troponin I (**TNI**) and **troponin C** (TNC) at 10 degrees and 20 degrees C with fluorescently labeled proteins. The sulfhydryl **probe** 5-iodoacetamidoeosin (IAE) was attached to cysteine (Cys)-98 of TNC and to Cys-133 of **TNI**, and each of the labeled proteins was titrated with the other unlabeled protein. The association constant for formation of the **complex** between labeled TNC (TNC*) and **TNI** was 6.67 X 10(5) M-1 in 0.3 M KCl, and pH 7.5 at 20 degrees C. In the presence of. . . of excess of Ca2+, the association constant was 5.58 X 10(9) M-1. Very similar association constants were obtained when labeled **TNI** was titrated with unlabeled TNC. The energetics of Ca2+ binding to TNC* and the **complex TNI** X TNC* were also determined at 20 degrees C. The two sets of results were used to separately determine the coupling **free** energy for binding **TNI** and Mg2+, or Ca2+ to TNC. The results yielded a total coupling **free** energy of -5.4 kcal. This **free** energy appeared evenly partitioned into the two species: **TNI** X TNC(Mg)2 or **TNI** X TNC(Ca)2, and **TNI** X TNC(Ca)4. The first two species were each stabilized by -2.6 kcal, with respect to the Ca2+ **free TNI** X TNC **complex**, and **TNI** X TNC(Ca)4 was stabilized by -2.8 kcal, respect to **TNI** X TNC(Ca)2 or **TNI** X TNC(Mg)2. The coupling **free** energy was shown to produce cooperatively **complexes** formed between **TNI** and TNC in which the high affinity sites were initially saturated as a function of **free** Ca2+ to yield **TNI** X TNC(Ca)4. This saturation occurred in the **free** Ca2+ concentration range 10(-7) to 10(-5) M. The cooperative strengthening of the linkage between **TNI** and TNC induced by Ca2+ binding to the Ca2+-specific sites of TNC may have a direct relationship to activation of. . .

AB A simple chromatographic procedure using DEAE-Sephadex has been established to isolate the troponin I-**troponin C** **complex** from **unbound** troponin I (**TnI**) and **troponin C** (TnC). A 1:1 **complex** can be formed between bovine cardiac carboxamidomethylated troponin I and rabbit skeletal **troponin C**. The formation of the **complex** is calcium dependent. It is stable to DEAE-chromatography in 6 M urea, 3 mM Ca2+ and can be dissociated on DEAE-chromatography in the presence of 6 M urea, 1 mM ethylene glycol bis(beta-aminoethyl ether)-N,N,N',N'-tetraacetic acid. TnC was modified with the photoaffinity **probe** AGTC (N-(4-azidobenzoyl-[2-3H]glycyl)-S-(2-thiopyridyl)-cysteine) at its single cysteine residue (position 98). Photolysis of the CM (carboxamidomethylated)-**TnI**-AGC-TnC **complex** resulted in the formation of a covalently linked 1:1 complex. The isolated covalently linked complex could be treated with dithiothreitol to reduce the disulfide bond between N-(4-azidobenzoyl-[2-3H]glycyl)-cysteine (AGC) and TnC to complete the transfer of the radiolabeled AGC from cysteine 98 on TnC to CM-**TnI**. The CM-**TnI**-AGC was isolated from TnC on DEAE-chromatography in 6 M urea, 1 mM EGTA, 1 mM dithiothreitol buffer.
The formation of the covalent bond between the photoaffinity **probe** and **TnI** indicates the close proximity of **TnI** to cysteine 98 on the TnC. These results demonstrate the general utility of the new heterobifunctional cross-linking reagent to study protein interactions.

AB We have determined the amino acid sequences of the essential light chains (ELC) and regulatory light chains (RLC) of myosin from two species of clam, Mercenaria mercenaria and Macrocallista nimbosa, using protein chemistry methods. The N-termini of all four proteins were blocked, and sequencing was carried out on various chemically and enzymatically produced peptide fragments. Cleavage of either Mercenaria RLC (MRLC) or Macrocallista RLC (VLC) at its 3 Arg yielded four peptides, three of which could not be sequenced directly, due to an N-terminal blocking group and 2 Arg-Gln bonds in these proteins. The fourth peptide was partially and specifically cleaved at an unusually reactive residue, Met-64, which is invariant in all known RLC sequences. A comparison of all available molluscan ELC and RLC sequences was carried out in search of clues to functionally important features of these proteins in muscles which are regulated by a Ca2+-sensitive myosin. By analogy with other RLCs, VRLC and MRLC may be phosphorylated at Ser-11 by an endogenous kinase. All myosin light chains, like **troponin C** and calmodulin, contain four homologous regions, I to IV, each of which contains a twelve-residue potential Ca2+-binding loop flanked on either side by a pair of helices. All RLCs, including those from Ca2+-insensitive myosins, contain a divalent cation-binding site in region I. Clam and other molluscan ELCs contain a single Ca2+-binding site in region III. This site is present only in the ELCs of myosins that are regulated by direct binding of Ca2+. The ELC site III is likely to play a key role in the regulation of molluscan muscle contraction.
